Side 2-2

```
public class Tax1 {
                                                                                                                                                                                                                                                                                                                                                                                                                           public static void main(String[] args) {
                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    Example: Calculation of AMBI and special pension payment
System.out.println(pension);
                                       System.out.print("Special pension payment: ");
                                                                             System.out.println(ambi);
                                                                                                                       System.out.print("AMBI: ");
                                                                                                                                                                                                             pension = income * 1.0 / 100.0;
                                                                                                                                                                                                                                                     ambi = income * 8.0 / 100.0;
                                                                                                                                                                                                                                                                                                                                         double ambi, pension;
                                                                                                                                                                                                                                                                                                                                                                                   int income = 120000;
```

©Haxthausen and Sestoft, IMM/DTU, 9. september 2002

02100+02115+02199+02312 Introductory Programming

Side 2-3

Output from the Tax1 program

AMBI: 9600.0

Special pension payment: 1200.0

Basic concepts: values and types

A (data) value can for instance be

• an integer (heltal): 120000

a floating point number (kommatal): 8.0

a character (tegn): '!'

• a Boolean (sandhedsværdi): false or true

• a character string (tegnstreng): "Bundskat: "

A (data) type is a family of values and operations on these.

©Haxthausen and Sestoft, IMM/DTU, 9. september 2002

02100+02115+02199+02312 Introductory Programming

Side 2-5

Types in Java

float, double are types of floating point numbers: e.g. -32.3, 1.0, 42.456, , 4.5E6, ... byte, short, int, long are types of integers: ..., -2, -1, 0, 1, 2, ...

char is the type of characters: 'a', ..., '1', ..., '!', ..., '\n',

boolean is the type of Booleans: true, false

String is a type of strings of characters: "Bundskat: ", "Peter", ...

String is not a primitive type, but a so-called class. More about that later

© Haxthausen and Sestoft, IMM/DTU, 9. september 2002

02100+02115+02199+02312 Introductory Programming

Side 2-6

Numeric values

In a computer every numeric value is represented as a binary number, i.e. combinations of bits (0 and 1).

Example: the numeric value 4 is represented as the binary number 100

value of that type. E.g. the type int uses 32 bit. See figure 2.4 of the book The various kinds of numeric values differ by the amount of memory space used to store a

Literals:

An integer like 17 is of type int.

An integer followed by 'L', e.g. 14084591234L, is of type long.

A floating point number like 17.2 is of type double.

A floating point number followed by 'F', e.g. 17.2F, is of type float

©Haxthausen and Sestoft, IMM/DTU, 9. september 2002

02100+02115+02199+02312 Introductory Programming

Side 2-7

Characters

In a computer every character is represented as an integer, e.g. 'A' is represented as 65.

on a screen or paper) A character set is a 'translation' from code (integers in the computer) to characters (graphics

Standard character sets: ASCII, ISO Latin1, Unicode Java uses Unicode.

©Haxthausen and Sestoft, IMM/DTU, 9. september 2002

02100+02115+02199+02312 Introductory Programming

Exercise: what are the types of the following values?

Value	Туре
58	
true	
-23	
"afd "	
42.0	
'\$'	
"42.0"	
"true"	
77'	

©Haxthausen and Sestoft, IMM/DTU, 9. september 2002

02100+02115+02199+02312 Introductory Programming

Side 2-9

Basic concepts: variable, declaration and assignment

A variable has a name and a location in the computer memory that can contain a value of a given type

A declaration gives a name and a type for one or more variables:

double ambi, pension;

The declaration also allocates space for the variables in the memory.

A declaration can contain an *initial value*: int income = 120000;

An assignment (tildelingssætning) assigns a value to a variable by storing the value in the

memory location belonging to the variable: ambi = income * 8.0 / 100.0;

© Haxthausen and Sestoft, IMM/DTU, 9. september 2002

02100+02115+02199+02312 Introductory Programming

Side 2-10

Basic concept: constants

A constant is similar to a variable, but it has the same value all the time.

Example of declaration:

final double AMBI_PROCENTAGE = 8.0;

Example of use:

ambi = income * AMBI_PROCENTAGE / 100.0;

©Haxthausen and Sestoft, IMM/DTU, 9. september 2002

02100+02115+02199+02312 Introductory Programming

Side 2-11

The state consists of the contents of the computer memory, output (on the screen), etc.

Basic concept: statements

A statement changes the state.

Example 1: an assignment can change the value of a variable:

pension = income * 1.0 / 100.0;

Example 2: a print statement can write on the screen:

System.out.print("Special pension payment: ");

Basic concept: expressions

An expression denotes (Danish: angiver) a value.

Example:

income * 8.0 / 100

Kinds of expressions:

- arithmetic expressions (denote numeric values)
- Boolean expressions (denote Boolean values)
- string expressions (denote string values)

©Haxthausen and Sestoft, IMM/DTU, 9. september 2002

02100+02115+02199+02312 Introductory Programming

Boolean expressions

More about that in chapter 3 (next lecture).

Side 2-13

©Haxthausen and Sestoft, IMM/DTU, 9. september 2002

02100+02115+02199+02312 Introductory Programming

Side 2-15

Arithmetic expressions

Are combinations of arithmetic operators and operands.

Operator Meaning	Meaning	Examples	ples
*	Multiplication	1.5 * 60.0	24 * 60
\	Division	13.0 / 2.0	13 / 2
0/0	Remainder	13.0 % 2.0	13 % 2
+	Addition	1.1 + 60.0	14 + 60
ı	Subtraction	1.1 - 60.0	134 - 60

you can write expressions representing strings of characters.

Like you can write arithmetic expressions representing numeric values,

String expressions

An important string operator:

string concatenation (+)

Result type is int if both arguments are int, otherwise double.

Read more on operator precedence and evaluation order in the book.

Example:

• "This is " + "course 02100"

(represents the string "This is course 02100")

©Haxthausen and Sestoft, IMM/DTU, 9. september 2002

Examples: Each expression has a type. • "This is " + "course 02100" has type String 1 + 2 has type int Types of expressions

Basic concept: data conversion

Values of one type can (in certain cases) be converted to another type:

- 1. Conversions between numerical types:
- (a) "widening": from a smaller type to a larger type (e.g. from int to double)
- (b) "narrowing": from a larger type to a smaller type (e.g. from **double** to **int**)
- 2. Conversion from any type to String type

In Java 1a and 2 is done automatically, but 1b can only be done explicitly by casting

© Haxthausen and Sestoft, IMM/DTU, 9. september 2002

02100+02115+02199+02312 Introductory Programming

Side 2-18

Examples of implicit widening conversion

```
money = 25.0;
                                                                                                                                                   money = money / 2; //now: money == 12.5
                                                                                                                                                                                                                                                                   dollars = money;
                                                                                                                                                                                                                                                                                                                                                                                      money = dollars; //now: money == 25.0
                                                                                                                                                                                                                                                                                                                                                                                                                             dollars = 25;
money = (int) money / 2; //now: money == 12.0
                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           double money; int dollars;
                                                                        //Here 2 is not converted:
                                                                                                                                                                                        // Second argument (2) of / is converted to a double (2.0):
                                                                                                                                                                                                                                                                                                                                                                                                                                                              //assignment conversion:
                                                                                                                                                                                                                                                                                                           //illegal assignment:

02100+02115+02199+02312 Introductory Programming

Example of conversion to a string

int x = 7;

System.out.println("the contents of x is: " + x);

Second argument of + is automatically converted to the string "7"

before it is concatenated with the first argument.

Output: the contents of x is: 7

Generally it holds for s + v and v + s,

where s is a string and v an expression of another type,

that $\ensuremath{\boldsymbol{v}}$ is automatically converted to its string representation.

Exercise: which values and types do the following expressions have?

Expression	Value of expression	Type of expression
1.5 * 60.0		
1.5 * 60		
24 * 60		
1.1 + 60 - 1		
150.0 / 60		
150 / 60		
134.0 % 60		
134 % 60		
"02199"		
"x is equal to "+ "0"		
"x is equal to "+ 0

Side 2-22

Short introduction to classes and objects

Informally

- A class represents a concept: time, appointment, car, cow, person, . .
- An object represents a thing, an instance of a concept: a particular time, a particular car, a particular cow, a particular person, . .
- A class has a collection of methods: those operations (functions) that can be applied to its objects.

In Java

- A class corresponds to a type, like int, double, boolean, ...
- An object corresponds to a value, like 17, 18.01, false, ...
- A method corresponds to an operation, like +, -, ...

©Haxthausen and Sestoft, IMM/DTU, 9. september 2002

02100+02115+02199+02312 Introductory Programming

Side 2-23

Three steps in using classes, objects and methods

- 1. Define a class (incl. its methods).
- Create objects of the class.
- 3. Use the methods of the objects

step one Some classes (e.g. String) are already defined in a class library. In that case you can skip

If a class has static methods, these can be used without step 2.

Definition of classes

Later you will learn how to define a class that contains declarations of:

- data (constants and variables)
- methods (each method is given a name and a sequence of statements, that have to be executed when the method is invoked.)

For now we will only use classes from libraries

For each class there is an interface informally describing the methods of the class:

name, argument types and a result type, and what happens when it is invoked.

Example: Extract of interface for String

int length() returns the number of characters in the string

char charAt (int index) returns the character at the specified index

Side 2-25

Creations of objects

An object is an instance of a class. It has data (e.g. a string) and methods as described by the

A variable contains either

- a primitive value, or
- a reference (henvisning) to an object.

Example: a variable containing a reference to an object of class String

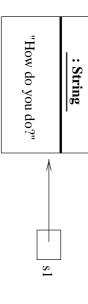

String s1 = "How do you do?";

02100+02115+02199+02312 Introductory Programming

Side 2-27

Use of methods

Invocation (kald) of the methods of an object is done with the dot operator.

Example: invocation of a String method

s1.length();

returns the value 14

(when the object, referenced to by s1, has the value "How do you do?").

Class libraries and packages

A class library is a collection of classes.

The classes are organized into various packages.

The most popular standard packages are

Package	Supports	Classes
java.lang	General stuff; automatically imported	Math, String, System
java.io	Input and output (e.g. to/from files)	:
java.util	General aux. classes	Random,

use an import statement, e.g.: To use a class of a package, you must either qualify the class name with the package name, or

```
import java.util.Random; // only the Random class
                                                                   import java.util.*; // all classes in the package
```

Input from the keyboard

```
static boolean readBoolean()
                                               The Keyboard class has methods for reading data from the keyboard
```

```
static String
                                 static long
                                                   static int
                                                                    static float
                                                                                    static double
                                                                                                      static char
                                                                                                                      static byte
                  static short
readString()
                 readShort()
                                                                   readFloat()
                                                                                    readDouble()
                                                                                                      readChar()
                                                                                                                      readByte()
                                 readLong()
                                                   readInt()
```

static means that methods can be invoked via their class name, e.g.

Keyboard.readBoolean()

The class can be copied from the cd of the book
